Improved measurements of the decay law and of the temperature dependence of the decay time and luminescent yield were made for two types of scintillations in pure CsI and NaI. The results show that the one type is described by a relatively simple model and may be explained, as already suggested for NaI, as the recombination of degenerated excitons, self-trapped in the crystal lattice. The other type of scintillations, (Physics--Solid State, TT, v. 8, no. 1) (over)
